

Welcome. This is the story of how our team took a public e-commerce dataset and turned it into a database and an interactive dashboard. Each stage fed the next.

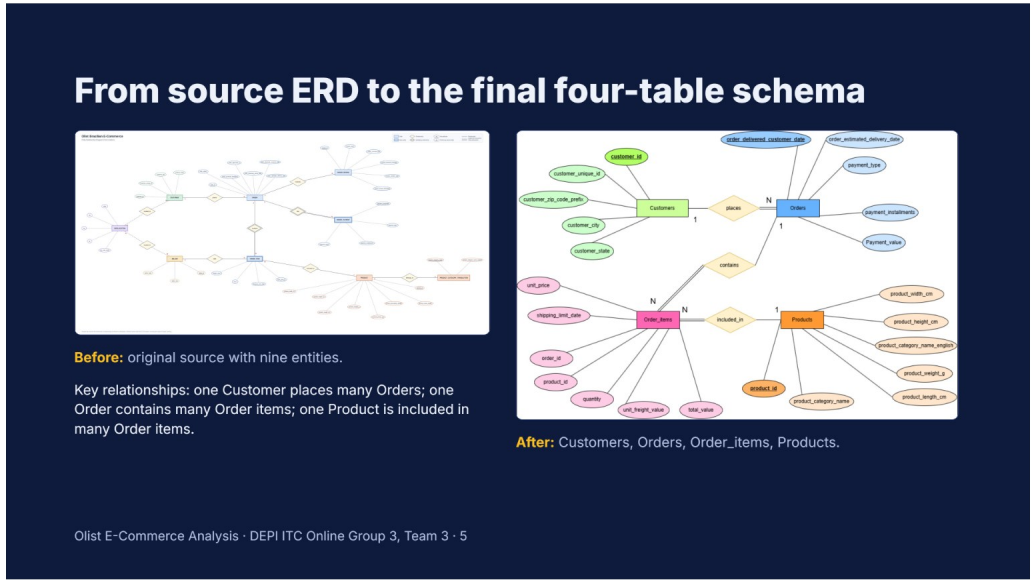

We chose Olist because it is a real, multi-table relational dataset. The five steps along the bottom are the order of the rest of this presentation.

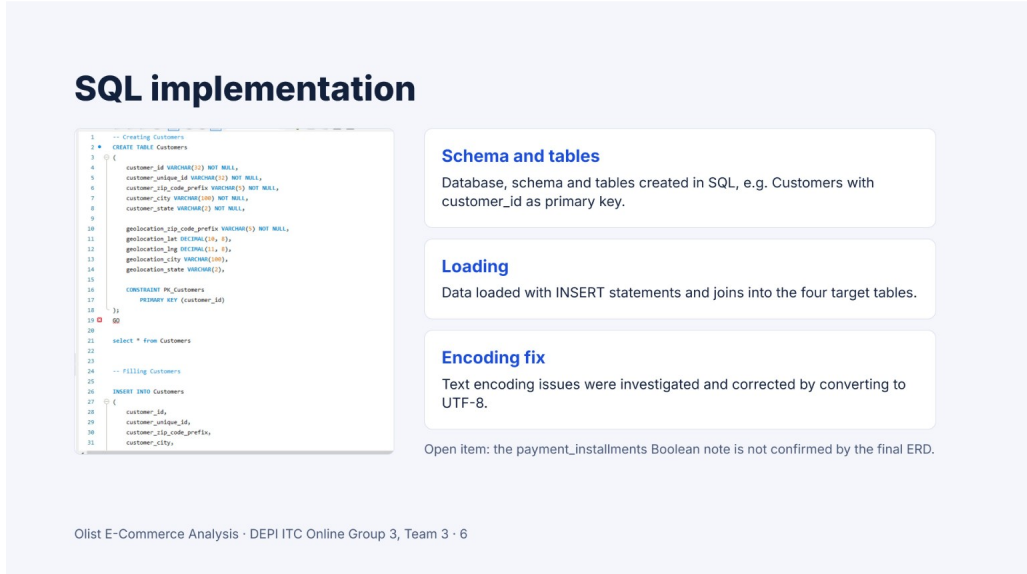

This is the ERD of the original dataset, drawn by Mahmoud Al-Nabawi, who also contributed to the data dictionary. It explains why the dataset is rich enough for the project. Do not confuse it with the final four-table design shown two slides later.

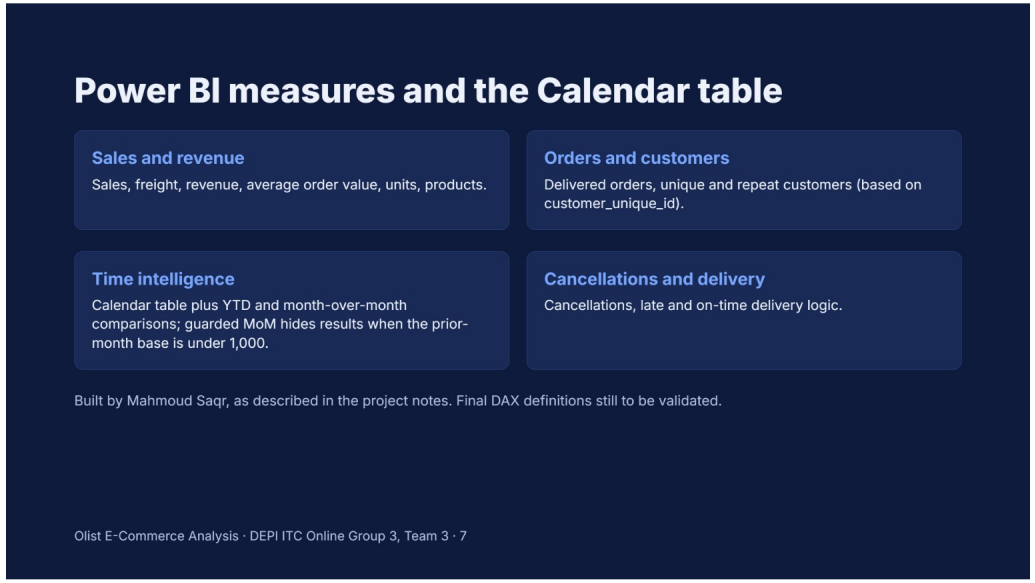

Mohamed El-Gml cleaned and prepared the data in a Python notebook. We deliberately do not quote error counts here, because they come from the generated quality report, which is not part of this deck.

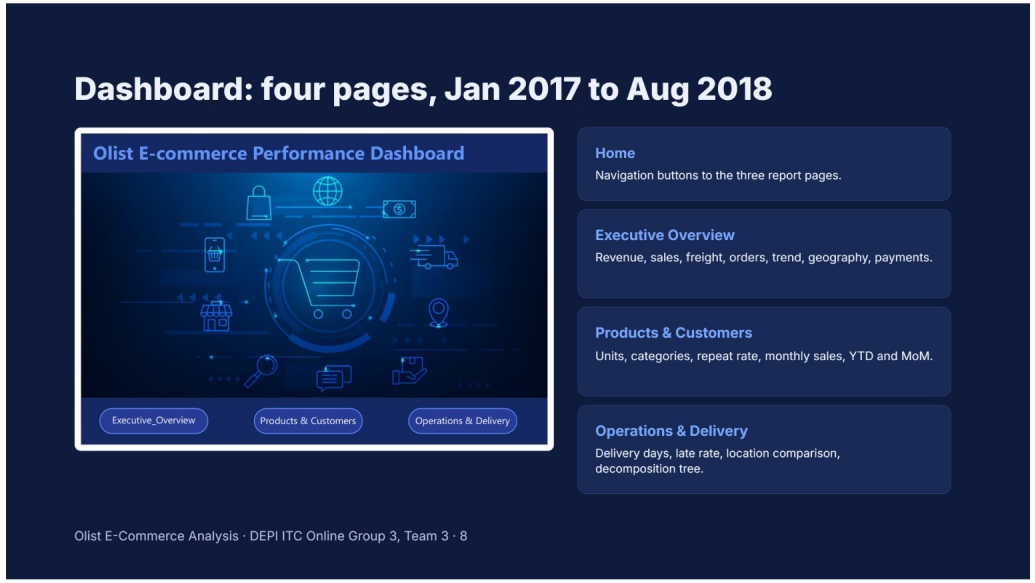

Left is the original source structure; right is the final database design with four tables. Mohamed Sokarno shaped the target design and considered normalisation, denormalisation and redundancy. A design note says payment_installments became a Boolean; the final ERD still lists it as an attribute, so we do not claim that change until it is confirmed.

Mohamed Sokarno created the database and loaded the data. The screenshot shows the Customers table definition. Validation of the load is described qualitatively only, since no row counts were supplied.

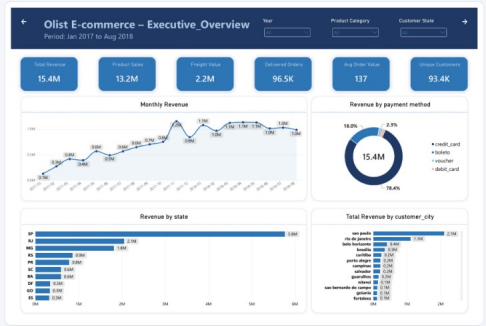

Mahmoud Saqr built the Calendar table and the measures. Using customer_unique_id matters because one person can have several customer_id values. The guarded MoM rule stops tiny early months from producing huge percentages.

Mostafa Salem built the four-page report. Slicers for Year, Product Category and Customer State filter every page.

Executive Overview

15.4M
Total revenue (13.2M product sales + 2.2M freight)

96.5K
Delivered orders; 93.4K unique customers

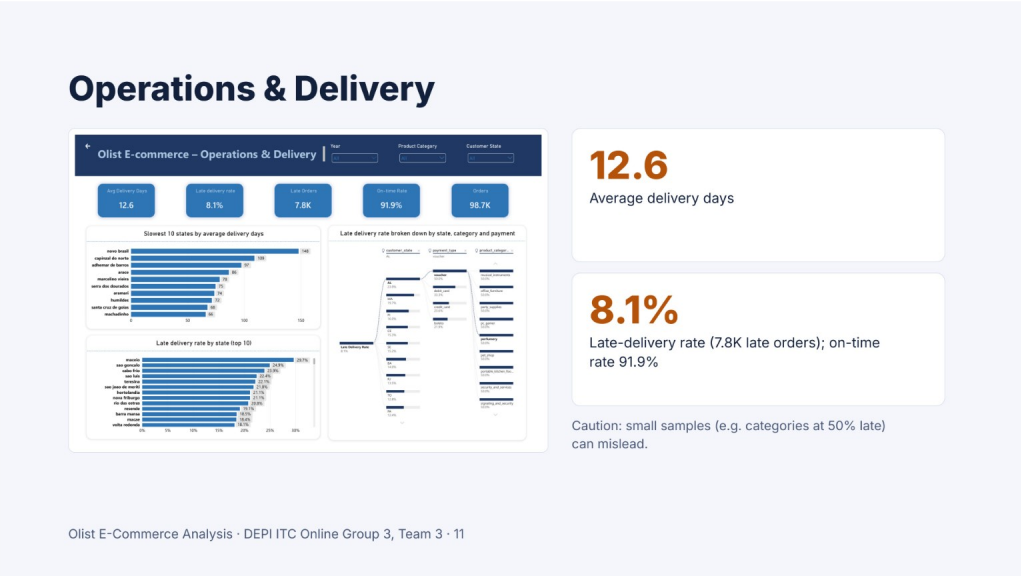

137
Average order value; 78.4% of revenue by credit card

Olist E-Commerce Analysis · DEPI ITC Online Group 3, Team 3 · 9

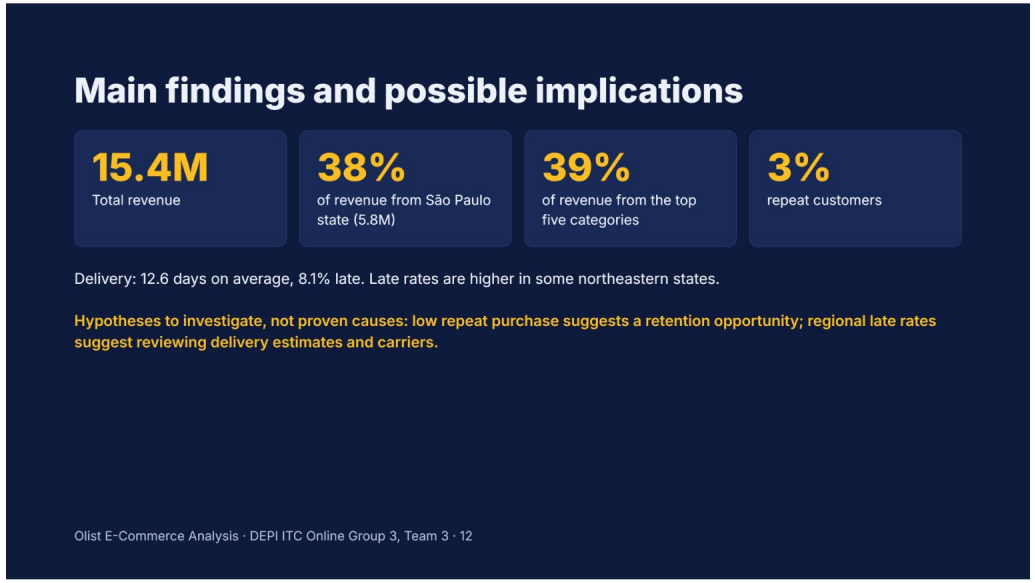

Headline view of the business. Currency is not stated on the dashboard, so we do not name one. São Paulo state leads with 5.8M in the state chart.

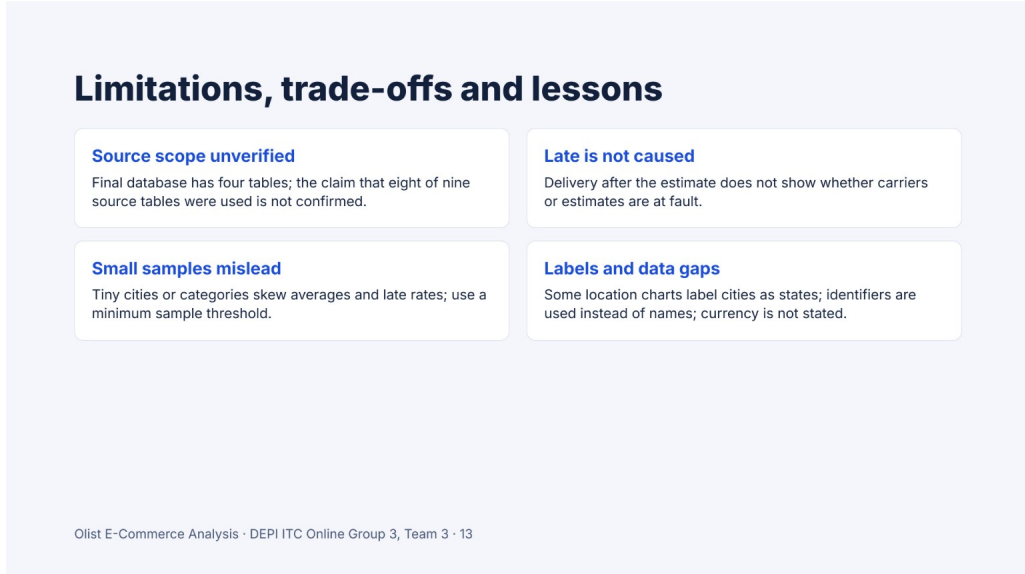

This page shows what sells and who buys. Repeat customers are only 3 percent, which is the most striking number here.

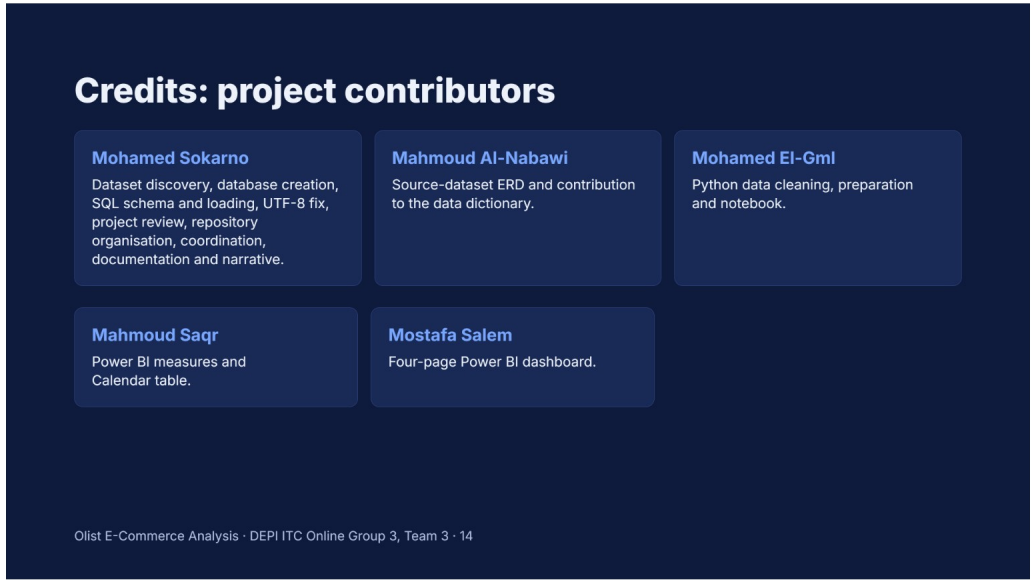

Operations view. Note the page's Orders count (98.7K) differs from Delivered Orders (96.5K) on the first page, so the bases are different.

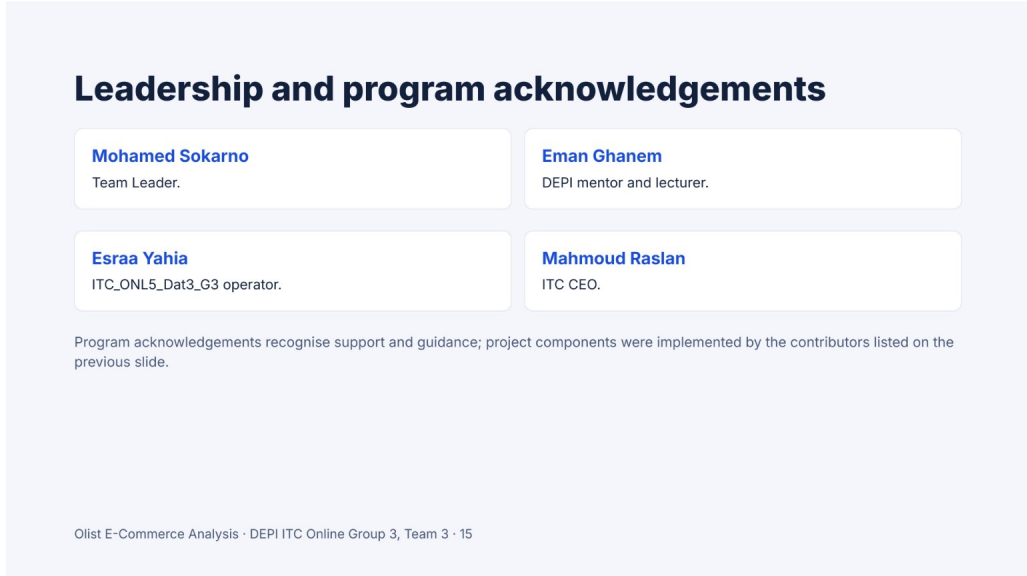

Figures were checked against the dashboard screenshots: 5.8M of 15.4M is about 38 percent, and the top five category shares add to about 39 percent. These are descriptive findings; the recommendations are hypotheses.

Be candid here. These limits shape how the dashboard should be read. Lesson learned: validate relationships and sample sizes before drawing conclusions.

Thank each contributor for their actual role.
